Abstract

Two on-farm experiments were conducted in Eastern Zimbabwe’s Chinyika Resettlement Area (18°02′ and 18°17′ S and 32°09′ and 32°24′ E), during 2002/2003 rainy season, to evaluate the effects of three grain legumes species, genotypes and cowpea (Vigna unguiculata L.Walp) populations on witchweed (Striga asiatica L Kuntze) emergence, growth, development and maize (Zea mays L.) grain yield. Both experiments were 2*3*3 factorial with three cropping systems being sole cowpeas, maize SC513 cowpea intercrop and maize Pan6363 cowpea intercrops. The cowpea genotypes were Kavara and IT18, while three cowpea populations were 55 000, 65 000 and 75 000 plants ha$^{-1}$. For experiment 2,. three legume species were soyabean [Glycine max (L.) Merill], cowpea and bambara nut [Vigna subterranea (L.) Verdc]. The cropping system, cowpea population, and genotypes significantly (P<0.001) affected Striga asiatica emergence across sites during 10 and 12 WACE. A significant interaction was observed between cropping system, genotypes, and cowpea populations. Maize SC513 intercropped with Kavara at 55 000 plants ha$^{-1}$ caused the highest Striga emergence, with Pan6363 Kavara intercrop at 55 000 plants ha$^{-1}$ having the lowest emergence. Maize SC513 IT18 intercrop at 55 000 plants ha$^{-1}$ caused the least emergence while Pan6363 IT18 intercrop at 55 000 plants ha$^{-1}$ had the highest emergence. A significant effect was observed between the two soyabean varieties, with Maize soyabean variety Magoye having the least emergence compared to Maize soyabean variety Hurungwe. Across sites, Striga emergence increased and reached peak emergence at 12 WACE, and then declined during 14 WACE within maize legume intercrops. Striga asiatica dry matter accumulation was low and significant (P<0.05) across sites. The cropping system had significant (P<0.05) effect on Striga asiatica days to flowering from emergence. Maize legume intercrops had more days to flowering from emergence. Maize grain yield, cob and maize plant height were negatively and weakly correlated to Striga asiatica emergence. Results indicate that sole legumes suppressed Striga asiatica emergence. Intercrop of cowpea genotype IT18 gave the least Striga asiatica emergence thus have a suppressive effect on to Striga asiatica parasitism. Smallholder farmers in Striga asiatica infested farms should therefore be encouraged to plant sole legumes in rotation with cereal crops to reduce Striga parasitism.
Acknowledgement

I thank my supervisor Professor O. A. Chivinge and Dr A.B. Mashingaidze for the guidance they provided. I also acknowledge the financial assistance provided by Rockefeller Foundation, Forum Programme.

I would want to thank the technicians, Mr S. Marimo, Mr N. Nyaruwata, Mr G. Parirenyatwa and the farmers for hosting the trials.

I would also want to mention and acknowledge the companionship and advice I enjoyed during my stay at Chinyika and of particular mention is Sydney Mavengahama and Maxwell Handiseni.

I would want to acknowledge the encouragement I got from my brothers, Jerry, Cadwell, Samuel, Hama, Nangisai, Shingirai and Shumba, my uncle. I wish to thank Mr G. Thole and Dr E. Garwe of Marirangwe Farm (Women’s University in Africa) for allowing me to use their computers. Thanks to Horticulture Research Centre, Marondera for availing computers.

I would like to thank my wife Anna for withstanding the long absence from home that characterized the studies and my son Rukudzo for enduring my absence from home.

Lastly I wish to salute my late parents for their positive attitude towards my studies, may their soul rest in eternal peace.
